Vaccine Project

Business Understanding

The client is a leader in the field of health care. The client has resources at their disposal that can be used to encourage non-vaccinated persons to become vaccinated. It would be beneficial to the client to know what groups of persons are less likely to be vaccinated in order to make the best use of the client's resources. Therefore, it would be helpful for the client to have a model that could predict which persons are less likely to be vaccinated based on various known factors, related to the person's background, views and behaviors, and also it would be helpful to know more generally which of these factors leads a group to be less or more likely to be vaccinated. This model and knowledge would facilitate efforts to reach persons individually and as groups in order to efficiently encourage vaccination.

Data Understanding

The data comes from the National 2009 H1N1 Flu Survey conducted by the United States after the outbreak of the virus in 2009. The survey covers various topics included one's background, views and behaviors. The survey also covers whether one has been vaccinated against the H1N1 virus, which will be the target variable for this project. More specifically, the potential predictor variables include socio-economic related factors, views about vaccines, and health-related behaviors and statuses (e.g., health insurance and doctor recommendation.) Given that H1N1 can be categorized as a risky virus, the data, though H1N1 specific, can be thought of as analagous to any risky virus such that insights from the data will be applicable to future viral outbreaks.

About half the features are categorical in nature as opposed to numerical. (Of the float and integer type features, about half are binary/categorical.) The columns with most missing data have about 10,000 of 27,000 missing. About 21% of respondents received the H1N1 vaccine.

Features with signficant correlation to the target variable are doctor reccomendation, opinion of virus risk, and opinion of vaccine effective.

See the data (./data).

Of the float and integer type features, about half are binary/categorical. The columns with most missing data have about 10,000 of 27,000 missing. About 21% of respondents received the H1N1 vaccine.

Some of the columns are not self-explanatory: census_msa, hhs_geo_region.

```
In [10]:  data.census_msa.value_counts()
```

Out[10]: MSA, Not Principle City 11645
MSA, Principle City 7864
Non-MSA 7198
Name: census_msa, dtype: int64

Metropolitan Statistical Area, it seems that these designation roughly mean: {MSA, Not Principle City: suburban; MSA, Principle City: urban; Non-MSA: rural }

hhs_geo_region, employment_industry, and employment_occupation are coded as random strings. Thus without decoding, they will provide little information.

Above, the survey seems to be fairly cross-sectional in terms of various background factors.

Check correlations with target variable and for multicollinearity.

Out[19]: <AxesSubplot:>

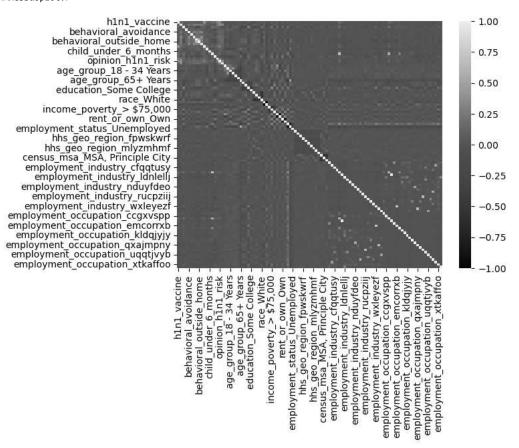

The potential predictor variables don't appear highly correlated amonst each other. Significant correlations appear to be: Doctor reccomendation, opinion of virus risk, opinion of vaccine effective.

Create dummy variables for each categorical variable so correlations/other calculations can be made.

Data Modeling

In the data modeling section, I start from a baseline logistic regression using three features and the response variable (whether the person has received the H1N1 vaccine). From there, I explore non-parametric models, starting with a fairly simple decision tree model. Based on the the results from this model, a more complex tree model is fitted and evaluated to achieve better results.

Check accuracies below:

```
Out[41]: 0.8197866256049274
Out[42]: 0.81326294952161
In [43]:  reg.decision_function(X_test)
   Out[43]: array([-2.46924764, -1.20906706, -1.40036619, ..., -2.27794851,
                 -0.56024581, -2.46924764])
Out[44]: array([[1.64255822, 0.42006019, 0.64882125]])
        Doctor recommendation appears to be the most important feature
In [45]: ▶ from sklearn.metrics import confusion_matrix
In [46]: Ŋ y_test_preds = reg.predict(X_test)
           cm = confusion_matrix(y_test, y_test_preds)
In [47]: ► cm
   Out[47]: array([[4415, 252],
                 [ 880, 515]], dtype=int64)
```

The number of false positives, 252, seems material but low, given the roughly 27,000 predicitions.

Non-parametric model: Decision Tree

Accuracy scores are very similar for test and train set (also to logistic regression). Since there does not appear to be any overfitting, it may make sense to build a more complex tree to try to pick up on more patterns in the training set.

Final model (tree and tuned)

Since there does not appear to be any overfitting, and possible underfitting, a more complex tree is used to produce better results.

Out[57]: 0.8155724183437809

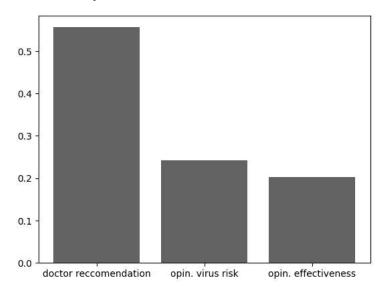

The accuracy scores in this more complex tree are highly similar to the initial tree, however the training and test scores have slightly improved and converged. This suggests that we now have a marginally improved model.

In [60]: ▶ from sklearn.metrics import ConfusionMatrixDisplay
```

Out[62]: array([[4401, 266], [852, 543]], dtype=int64)

Out[63]: <sklearn.metrics. plot.confusion matrix.ConfusionMatrixDisplay at 0x212c777fc40>

The confusion matrix is similar for both iterations of the tree model (269 false positives vs. 266 in final), as expected given there was only a slight improvement in accuracy. Compared to the baseline model, even though there are greater false positives, our greatest concern, our total correct predictions have increased. Thus even though the tree models would incorrectly classify more unvaccinated persons and therefore result in less resources for that population, given the higher accuracy on the test set of the big_tree model and the higher number of correct predictions (and lower false negatives) in our confusion matrix, resources would be better conserved and allocated by relying on the big_tree model.

Results, Recommendations, Limitations.

The results show that the big_tree model is the preferred model given its higher accuracy on the training and test sets compared to both the first tree iteration and the baseline logistic regression model. Given that this model performs better than the other models and better than the simple strategy of guessing the majority class for each prediction, it is recommended that this model be used to predict whether or not individuals have been given the a vaccine for any virus similar to H1N1, so that resources can be allocated efficiently based on one's vaccine status. More generally, the models show us that the three factors, presence of a doctor recommendation, opinion of virus risk, and opinion of vaccine effectiveness, are significantly related to whether one has received the vaccine. This suggest that it would be beneficial to both increase outreach to those with low presence of these factors and to provide outreach that could educate and provide resources so that such persons may become more likely to receive a vaccine.

The core limitation is that there is much room for improvement in the accuracy level of the final model. While the accuracy of the final model is 82%, a strategy of simply guessing that all persons have not received the vaccine would result in a similar 79% accuracy. Also note that iteratively, only slight improvement on models was made, given similar accuracies and only 1 more correct prediction in final model as compared to baseline.
